

Summary by Target Organ of National Cancer Institute/National Toxicology Program Bioassays in the Carcinogenic Potency Database

A chemical is listed under each target site evaluated by NCI as carcinogenic or NTP as “clear evidence” or “some evidence” of carcinogenic activity in at least one species. A chemical may be listed under several target organs in each species. An NCI evaluation that a site was “associated” with compound administration or an NTP evaluation of “equivocal” is not included in the table.

N = Number of chemicals in NCI/NTP bioassays with a target site in that species, either in males or females. The total number of chemicals that are positive in NCI/NTP bioassays is 174 for rats and 168 for mice.

In order to compare results in rats and mice, symbols follow chemicals tested in both species in NCI/NTP bioassays: [†] indicates that the chemical is positive at some site in both species, and [‡] indicates that it was tested by NCI or NTP in both species but was positive in only one species.

^a Nasal cavity includes tissues of the nose, nasal turbinates, paranasal sinuses and trachea.

^b Oral cavity includes tissues of the mouth, oropharynx, pharynx, and larynx.

If the NCI Technical Report indicated that tumors were “associated” with compound administration, these are not included in this table. For a few such cases, however, NTP assigned a “positive” evaluation, and noted that “these experiments were particularly difficult to evaluate based on the wording in the [NCI] Technical Report Summaries” (Haseman *et al.*, *Environ. Health Perspect.* 74: 229-235, 1987): 2-Amino-5-nitrothiazole (Hematopoietic system in rats), 5-Azacytadine (Hematopoietic system in mice), Butyl benzyl phthalate (Hematopoietic system in rats), Captan (Small intestine in mice), 2,4-Dinitrotoluene, practical grade (Mammary gland and Subcutaneous tissue in rats), Tetrachlorvinphos (Adrenal gland and Thyroid gland in rats) and Trimethylphosphate (Subcutaneous tissue in rats).
